Programmability: New Open Interfaces For SDN

Extending SDN Strategy with OpenFlow

- Support for OpenFlow across all Ethernet Switch products
- Powered by ExtremeXOS
- Will be available as a dynamically downloadable module
- Hybrid mode of operation

Open Multi-Vendor Approach to SDN

- Supporting multiple OpenFlow controllers

Extending SDN Strategy with Openstack

- Support for OpenStack Quantum with Plug-In

Creating SDN Developer Community Portal with XKit

- Launching Xkit for collaborative
- Programmable Network Applications

SDN (OpenFlow) Details

What is OpenFlow?

OpenFlow is a protocol that allows an external node to control the forwarding tables of a switch.

What is OpenFlow?

- Started 2008 at Stanford University
- Is now driven by Open Networking Foundation(ONF)
- ONF has over 70 members including:
 - Extreme Networks
 - Broadcom
 - Google
 - Microsoft
 - Yahoo
 - Facebook
 - Deutsche Telekom
 -

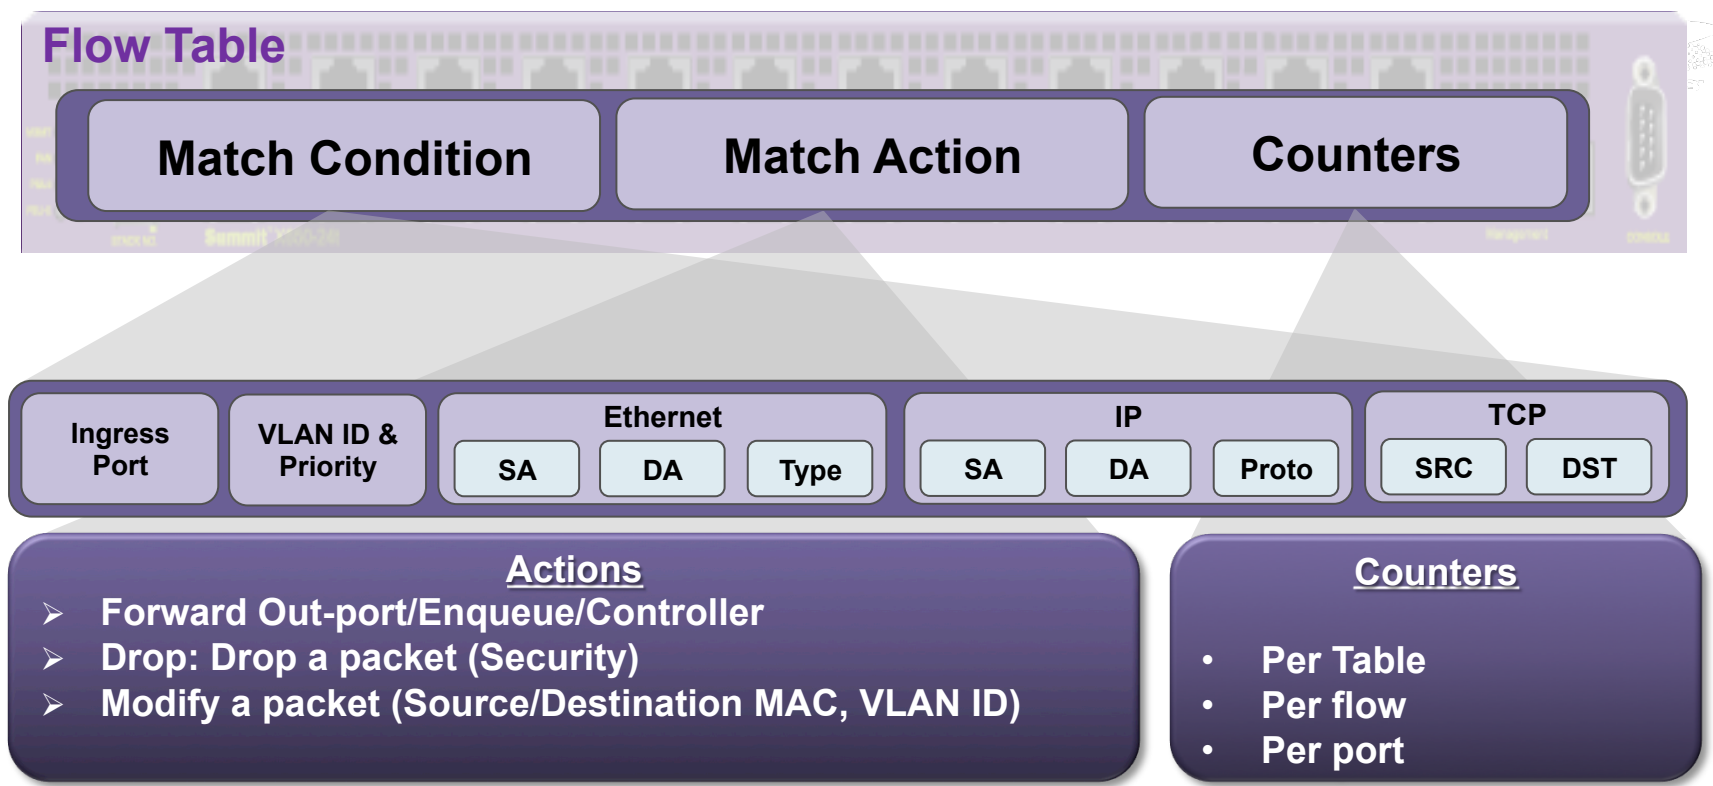

What is OpenFlow?

- Definitions:
 - **OpenFlow-only switch:** supports the mandatory client features of the OpenFlow protocol.
 - **OpenFlow-capable switch:** supports the mandatory client features of OpenFlow in addition to normal switch functions (e.g., STP, EAPS).
 - **Controller:** supports the server feature of the OpenFlow protocol. Manages the forwarding behavior of one or more OpenFlow switches.
 - **Flow entry:** the basic unit of forwarding management.
 - **Flow table:** consists of a set of priority ordered flow entries. A switch may support more than one flow table.
 - **Emergency flow table:** flow table that the switch uses in case connectivity with all configured controllers fails.
- A switch may simultaneously connect to multiple Controllers, but only one controller is master.
 - **Flowvisor:** can be used to slice a switch into multiple logical switches, each managed by a different Controller.

New Programmable Interfaces For SDN: OpenFlow

- OpenFlow 1.0 API XMOD; Hybrid Support
- OpenFlow controller redundancy; Out-of-band management port

Flow Entry Actions

- Forward: forward packet to the following physical or virtual ports:
 - Output port: forward to a specified physical output port
 - ALL: forward to all ports, excluding the incoming port
 - CONTROLLER: encapsulate packet (Packet-In message) and send it to the controller
 - LOCAL: forward via the switch's local networking stack
 - TABLE: perform actions in the flow table (for Packet-Out messages only)
 - IN_PORT: forward the packet back out of the incoming port
 - NORMAL (optional): forward according to the traditional forwarding path (e.g., generated by STP + learning)
 - FLOOD (optional): flood the packet along the minimum spanning tree, excluding the incoming port
- Drop: drop the packet
- Enqueue (optional): enqueue the packet in a specified output port queue.
- Modify-Field (optional): modify a header field

Flow Entry Modify Actions

- Set VLAN ID
- Set VLAN Priority
- Strip VLAN header
- Modify Ethernet MAC SA
- Modify Ethernet MAC DA
- Modify IPv4 SA (and update IPv4/TCP/UDP checksum)
- Modify IPv4 DA (and update IPv4/TCP/UDP checksum)
- Modify IPv4 ToS (DSCP)
- Modify TCP/UDP source port
- Modify TCP/UDP destination port

OpenFlow Startup Example

- Switch connects to controller. Both exchange Hello's. Version negotiation.
- Controller requests features with Features-Request.
- Switch responds with Features-Reply to indicate supported features and OpenFlow-enabled ports.

Topology OpenFlow Application Example

Switch and controller startup already complete.

SDN Community Portal – XKIT

Crowdsourcing, Network Applications store

Open Multi-vendor Approach

BigSwitch, NEC, Floodlight Controller etc.

Extending SDN with OpenStack

Network-as-a-service, Quantum Plugin

Enabling SDN with OpenFlow

OpenFlow 1.0 API, XMOD, Hybrid Support

Key SDN OpenFlow Features in EXOS

Open vSwitch (OVS) based OpenFlow

Robust implementation based on OVS Long Term Support (LTS)

Advanced Traffic Management

*Traffic distributed using LAG hashing
Queuing support based on EXOS profiles*

Multiple Tables for Deployment Flexibility

*FDB based flows for simple L2 flows – Higher Scale
ACL based flows for complex match & set conditions*

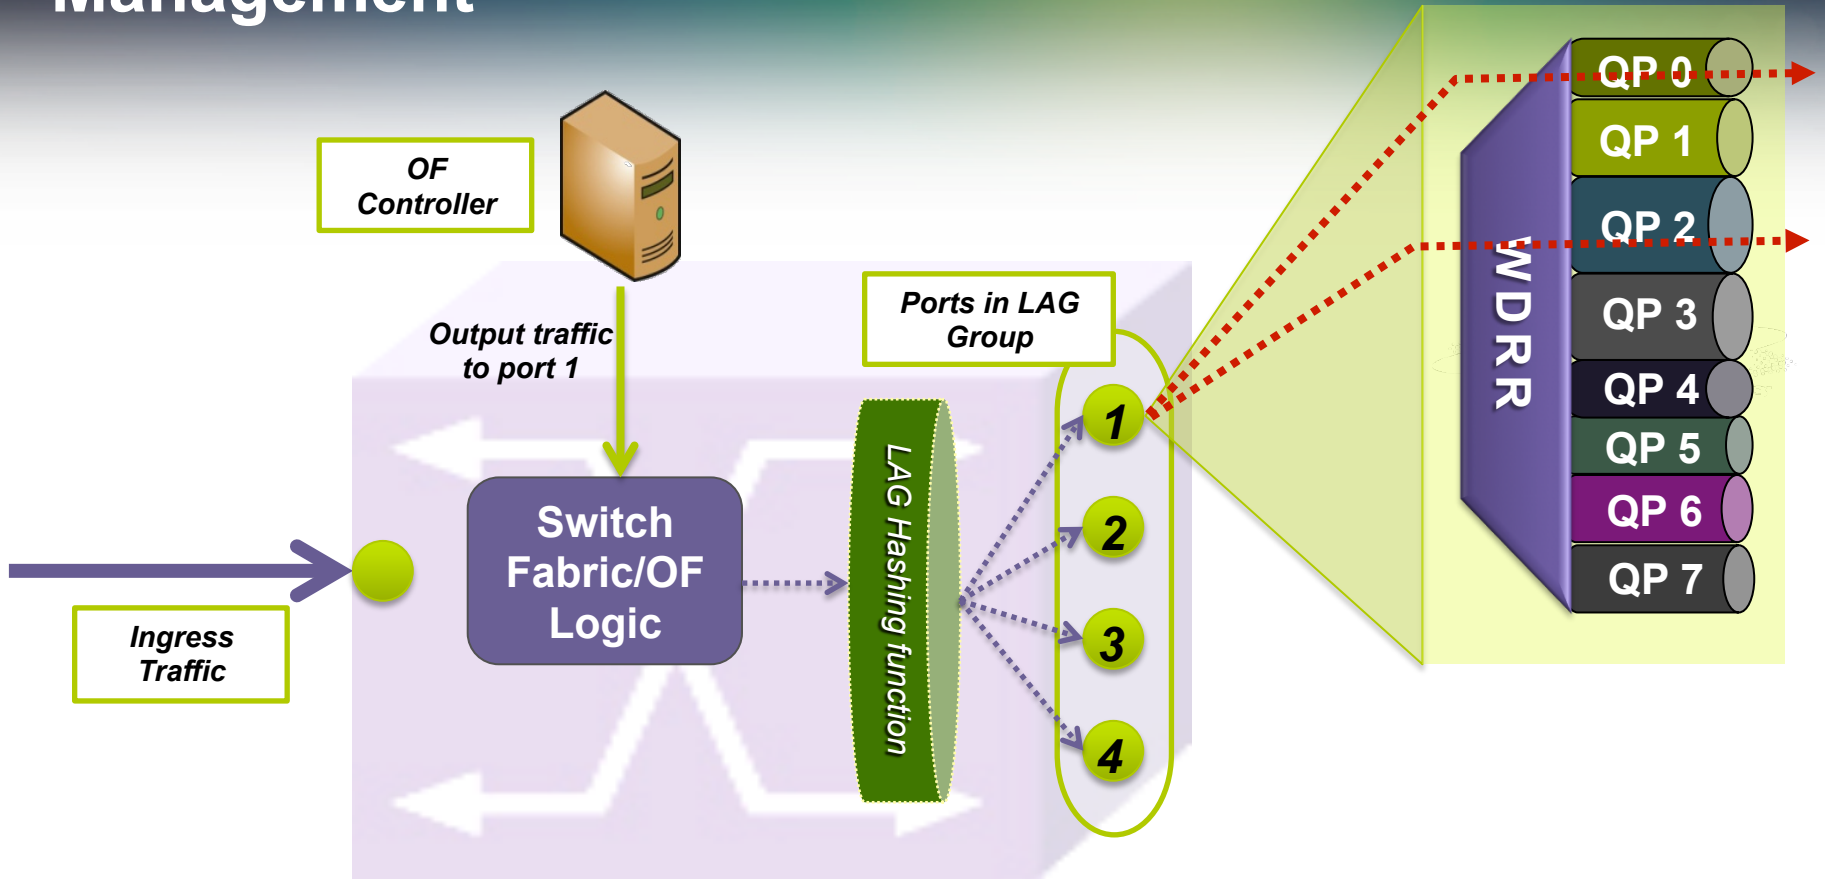

Multiple VLANs with Edit actions

*Simple OF based routing between VLANs
Support Applications requiring control of multiple VLANs*

MAC Address Rewrite

*Rewrite source and destination MAC
Support L3 SDN applications requiring MAC rewrite*

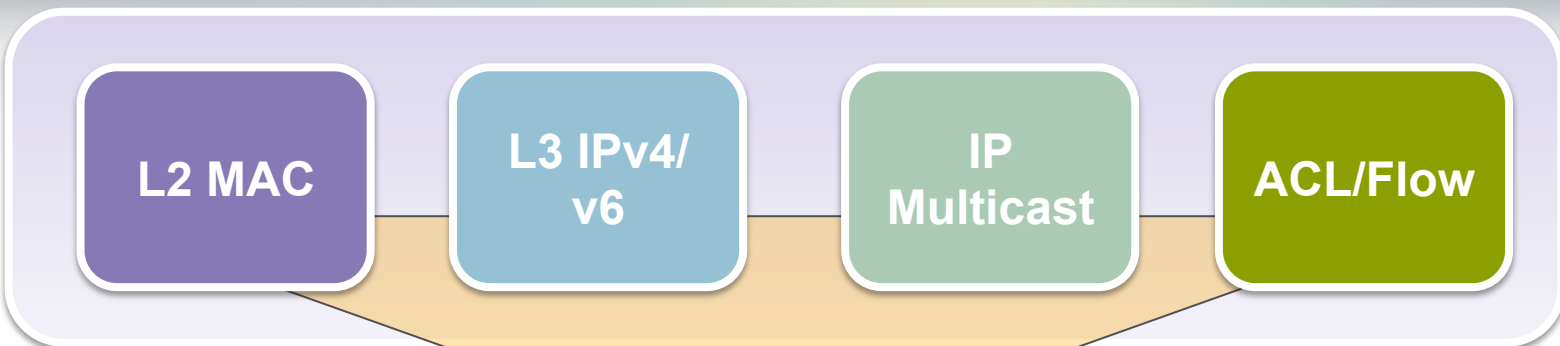

EXOS SDN Differentiation: Advanced Traffic Management

OpenFlow traffic distributed using LAG hashing function, instead of one port
OpenFlow traffic distributed through different QoS Profiles on egress port

SDN OpenFlow: Deployment Flexibility with Unified Forwarding Table

Legacy

*Optimal
Table
Utilization*

*SDN
Deployment
Profiles*

L2/L3 Balanced

L3 Heavy

Flow/ACL Heavy

SDN OpenFlow: Multiple Tables for Deployment Flexibility

OpenFlow needs flow oriented architecture scaling requirements

L2 MAC

FDB Tables can be used for macro flows that doesn't need finer-granular traffic control

L3 IPv4/v6

LPM Tables can be used for some complex flows involving IP address match conditions

ACL/Flow

ACL Tables can be used for micro flows that requires finer granular control of traffic with complex match and set conditions

OpenFlow abstracts all these tables into one table. From controller's perspective, OpenFlow behaves as if there is a single table

X-Kit: Application Portal

Crowd-Sourced Knowledge Base for SDN Applications

SDN Differentiations

Extreme Networks has specific capabilities that provide clear differentiation among competition. **Shipping TODAY !**

Hardware Link Aggregation

- EXOS represents the LAG as a single virtual interface to the OpenFlow controller enabling bandwidth scaling, load balancing and link redundancy

Hybrid Mode Support

- Standard Ethernet switching and OpenFlow based forwarding on a “per-vlan” basis.

Hardware Quality of Service

- Configured profile queues are reported to the OpenFlow controller, enabling flows to be programmed directly to hardware queues.

Automated Flow Management

- EXOS intelligently classifies and maps flows to hardware resources, both the ACL and FDB tables, allowing up to 100,000 flows per switch.

Software-Defined Networking: Myths vs. Reality

“SDN is just a research topic”

- ⇒ Seeing real production deployments for early adopters, moving to early majority

“OpenFlow can (can't) solve any real-world network problem”

- ⇒ OpenFlow is at version 1.0 and can solve a few problems well, but is expanding
- ⇒ Key point: it is a **control** (not a data) protocol

“SDN == OpenFlow”

- ⇒ OpenFlow is an *open, standard* protocol between the control & data planes in an SDN architecture

“SDN == Network Virtualization”

- ⇒ Network Virtualization is an important, key application for SDN, but others are possible

“We've been doing SDN with scripts for years...”

- ⇒ There has been a trend toward central controllers, but a programmable dataplane is different from configuration automation

“OpenFlow can't scale”

- ⇒ Google's entire datacenter backbone runs on OpenFlow 1.0

“SDN/OpenFlow deployment is rip-and-replace ”

- ⇒ All our current deployments have SDN/OpenFlow interoperating with existing networks

Architectural Disruptions

Open architectures bring waves of innovation

Networking

Looking to the Future of SDN and OpenFlow

OpenFlow becomes the Android of networking

- Open network OS and controller for Ethernet switches and routers
- OpenFlow and related specifications all available as Open Source

Apps for every need

- From QoS, to PBR, to Identity Management, to Mobility Management, to multi-tenancy and so on

Controller vendors eventually become application developers

- Apps come in free, premium, and freemium models

Switch vendors continue to build and sell switches

- Much like phone vendors continue to sell phones

App Stores and Marketplaces for OpenFlow and SDN Apps

And the Hardware.....?

.....still matters!
